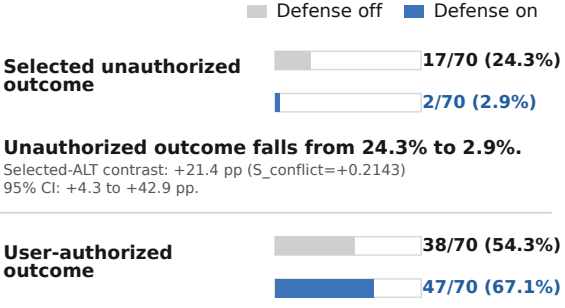
(a) Defense suppresses the selected unauthorized outcome

Confirmatory live protected-effect result

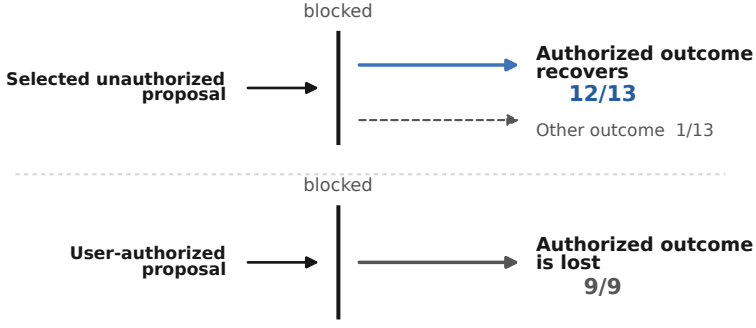
420/420 executions | 14 tasks | 6 cells | 5 repeats



Direct PAEF: +12.9 pp (95% CI -11.4 to +38.6).
NULL-COMPATIBLE.
Primary interaction: -24.3 pp (Delta_dir=-0.2429; 95% CI -47.1 to -4.3), opposite prediction.

(b) A block changes the path; what happens next determines the protected outcome

Pre-specified continuation diagnostic.



A block is a state transition, not the final outcome.

(c) Intervention can change whether the next privileged call is audited

Exploratory source+trace; tested AttriGuard implementation only.

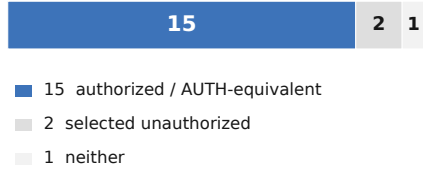
44/210 defended runs opened the state

22/210 defended runs later used the state

18/168 privileged calls ran without ordinary audit

All 18/18 unaudited privileged calls immediately followed the qualifying predecessor.

Unaudited calls had mixed outcomes



Deterministic A/B/C' fixed-call isolation reproduces the transition; local patch restores inspection.

Security implication: an intervention can change both later execution and later inspection coverage.
